The Problem:

A massive problem that Africa challenges is issues involving loadshedding, structural integrity of roads, railways and potholes. This creates a challenge for travelling of materials, packages and human vehicles from going to different places. These will be hard to solve. The main problem that this project will be solving consists of the flooded roads in Mozambique where the roads are filled with water, preventing people from going out and traveling or being able to get supplies such as food, clean drinking water and more.

The focus of this assignment will be travelling on flooded roads in Mozambique. Various obstacles of fallen items and floating along the road where you need to dodge obstacles. A way to solve this is to create a boat like vehicle that can change between a boat floating on the roads to a car on wheels. When it reaches the end of the 'level' it would be the end of the water-filled road and allowing the boat to turn into a moving car

Physics in the project will be used as water currents, creating the speed of the water drone in the simulation to go faster or slower depending on the direction of the water's flow, whether moving or not. When changing from side to side it should slow down the movement slightly before going to the side.

1.3 WIREFRAME & AI REFLECTION

WireFrame is a separate Image under the title of Wireframe.png.

1.3 AI is used ethically in this project through using it to help give a multitude of ideas on different wireframe ideas. Then it is used to compare the different options before mixing and matching the sets and creating the final design.

All AI logs are in the text file AIChatLog.txt.
